Dutcomes/Goals   1. Rapid identification and treatment of children with shunt or endoscopic third ventriculostomy (ETV) failure   2. Team-oriented approach to efficient, timely evaluation and workup   3. Decrease unnecessary radiation exposure   Patients aged ≤ 19 years with either a ventriculoperitoneal shunt or endoscopic third ventriculostomy (ETV) with symptoms of possible elevated intracranial pressure or shunt infection   Patients non-functional cerebrospinal fluid diverting shunts, patients with shunts or ETV presenting with symptoms not referable to their neurosurgical hardware   Chief complaint. Onset of symptoms. Vital Signs, including pain assessment. Last relevant surgical revision. Neuro exam, note any deviations from baseline. Activity level, LOC. Seizure history. History of fever, external shunt drainage, shunt or shunt tubing swelling, history of shunt infections, recent trauma. Assess for signs of increased intercranial pressure and meningismus. Document head circumference, and NPO status. If shunt, ask/document programmable vs nonprogrammable shunt (if known).  INTERVENTIONS   ESI Triage level II   Full set of vitals per standard of care Complete and fax MRI screening form   Place on continuous cardiac monitoring and document rhythm Notify LIP if hypertension, bradycardia, or decreased LOC noted Evaluate/consider Zofran for nausea/active vomiting Evaluate need for pain control   Patient may go to MRI off monitor if stable (no bradycardia, apnea, LOC changes or sedation)   Evaluate need for seizure pads NPO   Place topical Lidocaine (LMX) or J-tip order in anticipation of peripheral IV start   Elevate HOB 30 degrees   Elevate HOB 30 degrees   Elevate HOB 30 degrees   Elevate HOB 30 degrees   Elevate Mental status   Consider BMP if vomiting, altered mental status, lethargy, behavioral change, etc.   If concerns for infection, obtain CBC, CMP, CRP, ESR   EPHYSICIAN (LIP)   Physician   Plain films: shunt series (NOT REQUIRED FOR ETV) - must be done prior to MRI if shunt is	Suspected Shunt Malfunction/ETV Failure Clinical Pathway  June 2022

discharge.					

# **Clinical Pathway Decision Making Process**

Suspected Shunt Malfunction/ETV Failure Clinical Pathway

June 2022

# **Suspected Shunt Malfunction/ETV Failure Rationale and Data**

# **Goals of Clinical Pathway**

- 1. Rapid identification and treatment of children with shunt failure.
- 2. Team-oriented approach to efficient, timely evaluation and workup.
- 3. Identification of appropriate disposition.

### Definitions

<b>Definitions</b>				
Hydrocephalus	Lack of absorption, over-production, or obstruction of flow of CSF. May be present at birth			
	(congenital) or develop later in life (acquired). Occurs in approximately 1 out of every 1000			
	births. There is a 20-70% chance of developing hydrocephalus following intraventricular			
	hemorrhage.			
Communicating	Ventricles are open but reabsorption of CSF back into the venous system is obstructed.			
hydrocephalus	Commonly occurs secondary to hemorrhage or infection. Shunts are often employed to palliate.			
Noncommunicating	Obstruction within ventricular system, typically secondary to congenital malformation or			
hydrocephalus	neoplasm. May be palliated with a shunt or in some cases an endoscopic third ventriculostomy.			
Shunt Failure	Shunt failure rate is approximately 45-60% the first year following placement. Most common			
	reasons for failure of shunting are infection, obstruction and disconnection. Failure can occur as			
	a result of proximal malfunction (the intracranial catheter can become displaced, the valve can			
	fail), shunt tubing disruption, or distal malfunction (migration of abdominal catheter or			
	formation of CSF cyst at distal end with abdominal swelling, a so-called abdominal pseudocyst).			
ETV failure	The overall success rate of ETV six months after the procedure was 66% in one large multicenter			
	study; another large study yielded an 2-year operation-free survival of 58%.			
Signs and Symptoms of Elevated ICP				
Infant	Bulging fontanel, increasing head circumference, irritability, poor feeding, vomiting, scalp vein			
	distension, setting sun sign (upgaze paresis), episodic bradycardia, apnea, and excessive			
	sleepiness			
Child	Headache, vomiting, irritability, change in personality, change in cognition, lethargy,			
	hypersomnolence, discoordination, gait disturbance, seizure, nystagmus, upgaze paresis			
Shunt Infaction				

#### **Shunt Infection**

Fever, irritability, lethargy, erythema at insertion site or tracking along shunt tubing are common findings. Abscesses at the drainage site (abdominal) usually occur in first 1-3 months after placement. Shunt infection is almost always associated with shunt malfunction.

## **Abdominal Pseudocyst**

Abdominal pseudocysts are collections of fluid that develop at the tip of a ventriculoperitoneal shunt catheter within the peritoneum. They may be sterile or infected and typically cause predominantly abdominal symptoms such as distension, pain, nausea, vomiting, or constipation. A minority will also involve neurologic symptoms, though in one study half had increased ventricular size on neuroimaging.

## **Minimizing Ionizing Radiation**

Children with ventricular shunts are likely to receive dozens of CT scans over their lifetimes, significantly adding to the lifetime risk of malignancy. Given this, alternative modalities for evaluating for ventricular shunt failure have been explored. At current the most promising modality is 'quick' or 'rapid' brain MRI. Multiple studies have demonstrated that quick brain MRI has comparable sensitivity and specificity to CT for the evaluation of hydrocephalus in this patient population. At Doernbecher ED, quick brain MRI is the neuroimaging of choice for the stable patient being evaluated for shunt and ETV failure.
